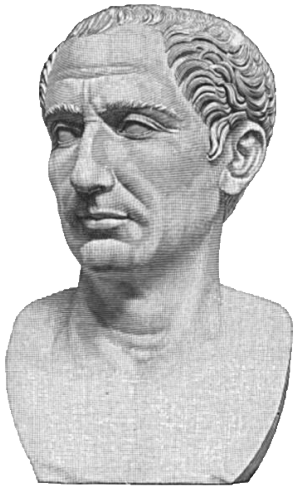
Caesar cipher



Methods for sending secret messages go back thousands of years. The idea is to send messages in a secret way so that they cannot be understood by an interceptor.

The Caesar cipher shifts every letter three places:

$$\begin{array}{ccccccccc} A & B & C & D & \cdots & W & X & Y & Z \\ \downarrow & \downarrow & \downarrow & \downarrow & \cdots & \downarrow & \downarrow & \downarrow & \downarrow \\ D & E & F & G & \cdots & Z & A & B & C \end{array}$$

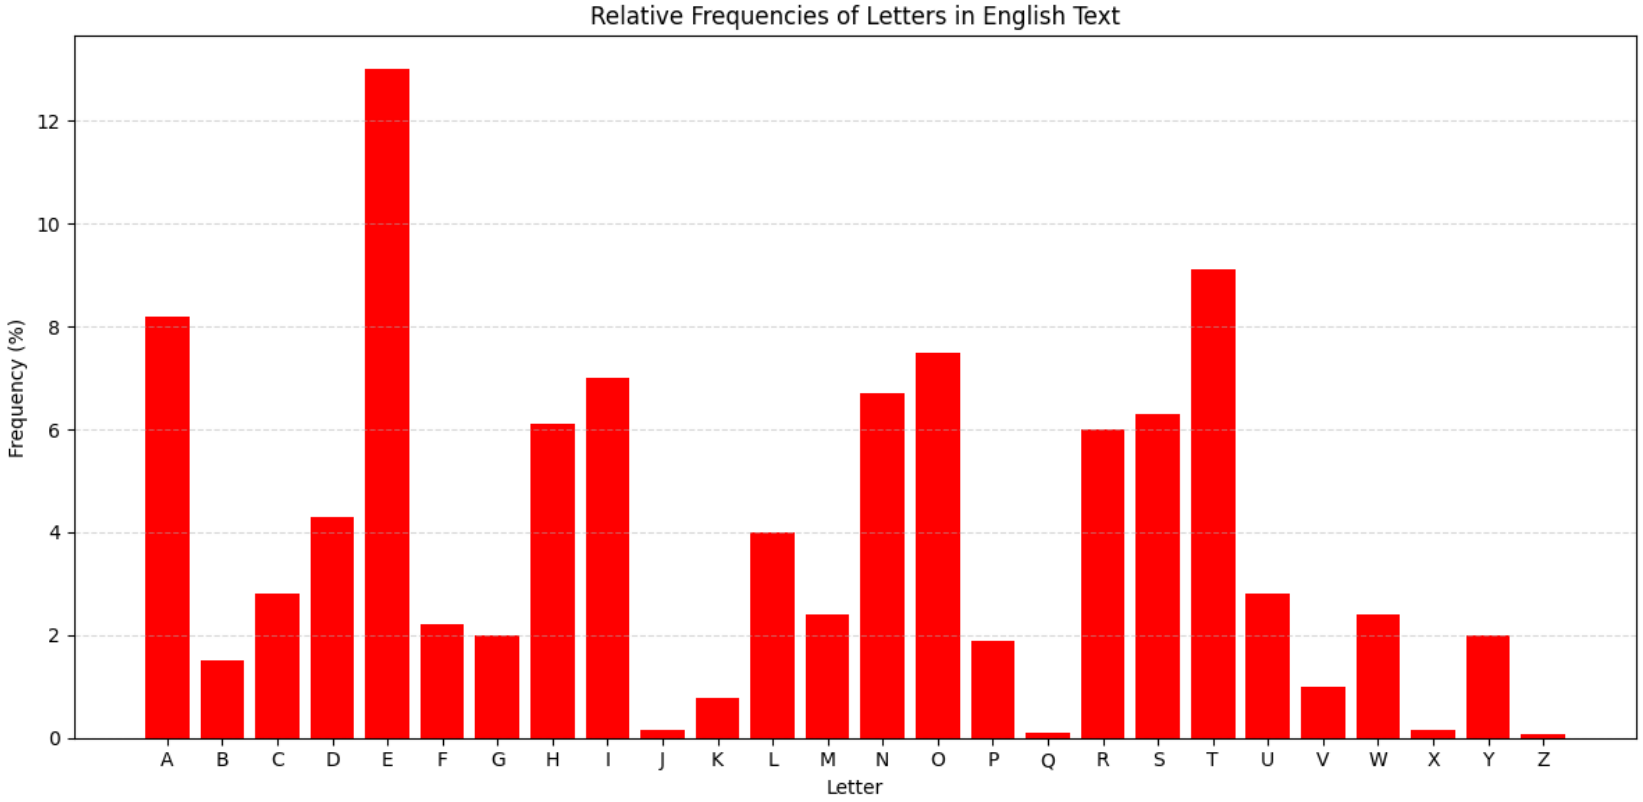
WAKE UP CALL is enciphered as ZDNH XS FDOO.

LQ D SLFNOH is deciphered as IN A PINCH.

In general, a shift cipher shifts each letter the same number of places.

Shift ciphers

Shift ciphers are easy to break because the letters in English follow a distinctive pattern of frequencies.



We can try out different possible shifts until these frequencies match the frequencies in the enciphered text.

Shift ciphers

Can we break this shift cipher?

Index of coincidence

Frequencies of letters in English are very far from a distribution that is chosen uniformly at random.

We can measure how close a distribution is to uniform by calculating the index of coincidence.

This measures the probability that when we randomly select a pair of letters from a text of N letters, the pair will be identical.

$$\text{Index of coincidence} = \frac{\#A(\#A-1)}{N(N-1)} + \cdots + \frac{\#Z(\#Z-1)}{N(N-1)}$$

Index of coincidence

If each letter in the text is chosen uniformly at random, the index of coincidence will be close to

$$\frac{1}{26} \approx 0.0385.$$

English text has a index of coincidence that is closer to 0.0700.

Any text enciphered with a shift cipher will also have a index of coincidence close to 0.0700.

Vigenère cipher

The Vigenère cipher was regarded as being unbreakable between 1550 and 1850 (approximately). To encode, we follow these steps:

- Choose a key word. E.g. ALERT
- Repeat the key below the input text.
- Shift each letter by the number of places corresponding to that letter of the key.

Input:	*A*	*T*	*T*	*A*	*C*	*K*		*A*	*T*		*D*	*A*	*W*	*N*
Key:	*A*	*L*	*E*	*R*	*T*	*A*		*L*	*E*		*R*	*T*	*A*	*L*
Shift:	0	11	4	17	19	0		11	4		17	19	0	11
Output:	*A*	*E*	*X*	*R*	*V*	*K*		*L*	*X*		*U*	*T*	*W*	*Y*

Breaking the Vigenère cipher

This text has been enciphered using the Vigenère cipher. Can we break it?

Breaking the Vigenère Cipher

If the key word has length K, then every Kth letter is enciphered using the same shift.

Extracting every Kth letter should produce a distribution that is close to the English alphabet.

We can detect this by calculating the index of coincidence.

Breaking the Vigenère Cipher

Once we have guessed key length K, we need to find the key word.

Letters in positions 0, K, $2K$, $3K$, ... are all shifted by the same number. We can guess this shift by comparing frequencies.

Letters in positions 1, $K+1$, $2K+1$, $3K+1$, ... are shifted by the same number, so we repeat this procedure.

In this way, we can guess the key word.

Thanks for listening!

Code used in this demonstration can be found here:
